

# Übungsblatt 0 zu “Programmiersprachen”

Berthold Hoffmann, Studiengang Informatik ([hof@informatik.uni-bremen.de](mailto:hof@informatik.uni-bremen.de))

Besprechung am 7. 4. 2010

## Was sind Zählschleifen?

Untersuchen Sie *Zählschleifen* in den Referenzsprachen *Ada*, *Eiffel* und *Java*. (Da Schleifen auf Zuständen basieren, macht es wenig Sinn, sie in den funktionalen Referenzsprachen *Haskell* und *SML* oder in *Prolog* zu suchen.)

Als einmaliger Service des Veranstalters (*Applaus, bitte!*) sind hier schon die passenden Auszüge aus den Sprachbeschreibungen von Ada und Eiffel eingefügt. Die Definition von Zählschleifen in *Java* sollte vertraut sein, oder es sollte klar sein, wo sie zu finden ist.

### Zählschleifen in Ada

[Aus: *Ada 95 Reference Manual*, Abschnitt 5.5 *Loop Statements*, <http://www.adahome.com/rm95/>]

A loop\_statement includes a sequence\_of\_statements that is to be executed repeatedly, zero or more times.

#### Syntax

```
loop_statement ::=  
    [loop_statement_identifier:]  
    [iteration_scheme] loop  
        sequence_of_statements  
    end loop [loop_identifier];  
  
iteration_scheme ::= while condition  
    | for loop_parameter_specification  
  
loop_parameter_specification ::=  
    defining_identifier in [reverse] discrete_subtype_definition
```

**Anmerkung.** Eine discrete\_subtype\_definition definiert eine Teilmenge eines diskreten Typs. In Ada sind die Aufzählungstypen und ganzzahlige Typen diskret (und deren Untertypen). Die Typen Character und Boolean sind Aufzählungstypen. Teilmengen können direkt angegeben werden durch einen Teilbereich (discrete\_range) der Form **range** *ugr* .. *ogr*, wobei *ugr* und *ogr* Ausdrücke desselben diskreten Typs sind. Die Spezifikation **reverse range** besagt, dass die Elemente des Teilbereichs *range* in umgekehrter Reihenfolge durchlaufen werden.

If a loop\_statement has a loop\_statement\_identifier, then the identifier shall be repeated after the **end loop**; otherwise, there shall not be an identifier after the **end loop**.

## Static Semantics

A `loop_parameter_specification` declares a loop parameter, which is an object whose subtype is that defined by the `discrete_subtype_definition`.

## Dynamic Semantics

For the execution of a `loop_statement`, the `sequence_of_statements` is executed repeatedly, zero or more times, until the `loop_statement` is complete. The `loop_statement` is complete when a transfer of control occurs that transfers control out of the loop, or, in the case of an `iteration_scheme`, as specified below.

For the execution of a `loop_statement` with a `while iteration_scheme`, the condition is evaluated before each execution of the `sequence_of_statements`; if the value of the condition is True, the `sequence_of_statements` is executed; if False, the execution of the `loop_statement` is complete.

For the execution of a `loop_statement` with a `for iteration_scheme`, the `loop_parameter_specification` is first elaborated. This elaboration creates the loop parameter and elaborates the `discrete_subtype_definition`. If the `discrete_subtype_definition` defines a subtype with a null range, the execution of the `loop_statement` is complete. Otherwise, the `sequence_of_statements` is executed once for each value of the discrete subtype defined by the `discrete_subtype_definition` (or until the loop is left as a consequence of a transfer of control). Prior to each such iteration, the corresponding value of the discrete subtype is assigned to the loop parameter. These values are assigned in increasing order unless the reserved word `reverse` is present, in which case the values are assigned in decreasing order.

## NOTES

1. A loop parameter is a constant; it cannot be updated within the `sequence_of_statements` of the loop (see 3.3).
2. An `object_declaration` should not be given for a loop parameter, since the loop parameter is automatically declared by the `loop_parameter_specification`. The scope of a loop parameter extends from the `loop_parameter_specification` to the end of the `loop_statement`, and the visibility rules are such that a loop parameter is only visible within the `sequence_of_statements` of the loop.
3. The `discrete_subtype_definition` of a `for` loop is elaborated just once. Use of the reserved word `reverse` does not alter the discrete subtype defined, so that the following `iteration_schemes` are not equivalent; the first has a null range.

```
for J in reverse 1 .. 0
  for J in 0 .. 1
```

## Examples

...

Example of a loop statement with a `for iteration_scheme`:

```
for J in Buffer'Range loop -- works even with a null range
  if Buffer(J) /= Space then
    Put(Buffer(J));
  end if;
end loop;
```

...

## Zählschleife in Eiffel

[Aus: *Chapter H: An Eiffel Tutorial, Eiffel—The Language* von Bertrand Meyer, Seite 1009–1010, <http://www2.inf.ethz.ch/~meyer/ongoing/etl/>.]

...

The loop construct has the form

```
from
    initialization
until
    exit
invariant
    inv
variant
    var
loop
    body
end
```

[1] The invariant *inv* and variant *var* parts are optional, the others required. *initialization* and *body* are sequences of zero or more instructions; *exit* and *inv* are boolean expressions (more precisely, *inv* is an assertion); *var* is an integer expression.

The effect is to execute *initialization*, then, zero or more times until *exit* is satisfied, to execute *body*. (If after *initialization* the value of *exit* is already true, *body* will not be executed at all.) Note that the syntax of loops always includes an initialization, as most loops require some preparation. If not, just leave *initialization* empty, while including the **from** since it is a required component.

The assertion *inv*, if present, expresses a loop invariant (not to be confused with class invariants). For the loop to be correct, *initialization* must ensure *inv*, and then every iteration of *body* executed when *exit* is false must preserve the invariant; so the effect of the loop is to yield a state in which both *inv* and *exit* are true. The loop must terminate after a finite number of iterations, of course; this can be guaranteed by using a loop variant *var*. It must be an integer expression whose value is non-negative after execution of *initialization*, and decreased by at least one, while remaining non-negative, by any execution of *body* when *exit* is false; since a non-negative integer cannot be decreased forever, this ensures termination. The full-assertion-monitoring mode will check these properties of the invariant and variant after *initialization* and after each loop iteration, triggering an exception if the invariant does not hold or the variant is negative or does not decrease.

...

*Beispiel (von Seite 1002):*

```
local
    s: SAVINGS_ACCOUNT
do  from account_list start until account_list after loop
    s ?= acc_list item
        -- item from LIST yields the element at cursor position
    if s /= Void and then s interest_rate > Result then
        Result := s interest_rate
    end
    account_list forth
end
end
```

## Aufgaben

1. Schreiben Sie – soweit das möglich ist – folgende Arten von Zählschleifen in den Sprachen *Java*, *Ada* und *Eiffel* (begründen Sie andernfalls bitte, weshalb es *nicht* möglich ist):
  - (a) Die Zählvariable durchläuft die Werte 1, 2, 3, 4, 5.
  - (b) Die Zählvariable durchläuft die Werte 50, 40, 30, 20, 10.
  - (c) Eine nicht terminierende Zählschleife.
2. Beantworten Sie die folgenden Fragen für beliebige Zählschleifen in den Sprachen *Java*, *Ada* und *Eiffel*:
  - (a) Wie oft wird der Ausdruck ausgewertet, mit dem der Endwert für die Zählvariable festgelegt wird?
  - (b) Darf die Zählvariable im Schleifenrumpf verändert werden?
  - (c) Ist die Folge der Werte  $v_1, \dots, v_n$ , die der Zählvariable zugewiesen werden vor der ersten Ausführung des Schleifenrumpfes bekannt?  
(Damit wäre auch die maximale Anzahl  $n$  dieser Werte und die maximale Anzahl der Schleifendurchläufe bekannt.)  
*Zusatzfrage:* Weshalb wäre allenfalls die *maximale* Anzahl bekannt?
  - (d) Welchen Wert hat die Zählvariable, nachdem die Schleife verlassen wurde?
3. Bewerten Sie die Konzepte und ihre Beschreibung in *Java*, *Ada* und *Eiffel*:
  - (a) Welche Zählschleifen halten Sie für die Beste?
  - (b) Weshalb?
  - (c) Welche der Beschreibungen halten Sie für die beste?
  - (d) Weshalb?
